BACS HW 4

Question 1) Let's reexamine how to *standardize* data: subtract the mean of a vector from all its values, and divide this difference by the standard deviation to get a vector of standardized values.

- a) Create a normal distribution (mean=940, sd=190) and standardize it (let's call it rnorm_std)
 - i) What should we expect the mean and standard deviation of rnorm_std to be, and why?
 - ii) What should the distribution (shape) of rnorm_std look like, and why?
 - iii) What do we generally call distributions that are normal and standardized?
- b) Create a standardized version of minday <u>discussed in question 3</u> (let's call it minday_std)
 - i) What should we expect the mean and standard deviation of minday_std to be, and why?
 - ii) What should the distribution of minday std look like compared to minday, and why?

Question 2) Install the compstatslib package from Github (see class notes) and run the plot_sample_ci() function that simulates samples drawn randomly from a population. Each sample is a horizontal line with a dark band for its 95% CI, and a lighter band for its 99% CI, and a dot for its mean. The population mean is a vertical black line. Samples whose 95% CI includes the population mean are blue, and others are red.

- a) Simulate 100 samples (each of size 100), from a normally distributed population of 10,000: visualize_sample_ci(num_samples = 100, sample_size = 100, pop_size=10000, distr func=rnorm, mean=20, sd=3)
 - i) How many samples do we *expect* to NOT include the population mean in its 95% CI?
 - ii) How many samples do we expect to NOT include the population mean in their 99% CI?
- b) Rerun the previous simulation with the same number of samples, but larger sample size (sample size=300):
 - i) Now that the size of each sample has increased, do we expect their 95% and 99% CI to become wider or narrower than before?
 - ii) This time, how many samples (out of the 100) would we *expect* to NOT include the population mean in its 95% CI?
- c) If we ran the above two examples (a and b) using a uniformly distributed population (specify parameter distr_func=runif for plot_sample_ci), how do you *expect* your answers to (a) and (b) to change, and *why*?

Question 3) The company EZTABLE has an online restaurant reservation platform that is

We have a *sample* of data about their <u>new members</u>, in particular the date and time for which they make their <u>first ever booking</u> (i.e., the booked time for the restaurant) using the EZTABLE platform. Here is some sample code to explore the data:

```
bookings <- read.table("first_bookings_datetime_sample.txt", header=TRUE)
bookings$datetime[1:9]
   [1] 4/16/2014 17:30  1/11/2014 20:00  3/24/2013 12:00 ...
   18416 Levels: 1/1/2012 17:15 1/1/2012 19:00 ... 9/9/2014 19:30
hours <- as.POSIXlt(bookings$datetime, format="%m/%d/%Y %H:%M")$hour
mins <- as.POSIXlt(bookings$datetime, format="%m/%d/%Y %H:%M")$min
minday <- hours*60 + mins
plot(density(minday), main="Minute (of the day) of first ever booking", col="blue", lwd=2)</pre>
```

- a) What is the "average" booking time for new members making their first restaurant booking? (use minday, which is the absolute minute of the day from 0-1440)
 - i) <u>Use traditional statistical methods</u> to estimate the *population mean* of minday, its *standard error*, and the *95% confidence interval* (CI) of the sampling means
 - ii) Bootstrap to produce 2000 new samples from the original sample
 - iii) Visualize the means of the 2000 bootstrapped samples
 - iv) Estimate the 95% CI of the bootstrapped means using the quantile function
- b) By what time of day, have half the new members of the day already arrived at their restaurant?
 - i) Estimate the *median* of minday
 - ii) Visualize the *medians* of the 2000 bootstrapped samples
 - iii) Estimate the 95% CI of the bootstrapped medians using the quantile function

Here's a hint if you are having trouble figuring out how to do bootstrapping for this week's assignment, you may start by considering this function:

```
compute_sample_mean <- function(sample0) {
  resample <- sample(sample0, length(sample0), replace=TRUE)
  mean(resample)
}</pre>
```

If you run compute_sample_mean(minday) then you will get a new sample's mean from minday. You could then use the replicate() function to run this function 2000 times for bootstrapping.
